Sprint 1 Retrospective

Heads up

After doing the entire thing I realized the core technologies for Web are React Router, Tailwind CSS but this is done in mainly html, JavaScript, and some CSS on visual studio code.

Sprint goal

Set up the foundations of AL-Web: a secure place to store users, sign-up and login with role-based access for brokers and bank underwriters, and a first view of the origination pipeline for each role.

What was delivered

Feature	What was built	Status
1. User data and storage	Connected to the team's shared Firebase project. Users are stored in Firebase Authentication (password hashed) and in the Firestore users collection (email, name, role). Security Rules written for users and application.	Done
2. Authentication and role-based access	Home page, sign-up and login with Broker / Bank Underwriter buttons. Each role lands on its own page, wrong roles are refused, logged-out users are redirected to login, and Log out works.	Done
3. Origination pipeline view	Broker and Underwriter Pipeline pages showing status, LTV and risk tier using sample data. Filters are shown but not working yet.	Partly done

Testing: 16 test cases were written and run. 15 passed. Feature 1 was tested live against the team's Firebase project, and Features 2 and 3 were tested on the real pages with screenshots for each test case.

What went well

- Login and role checks worked first time against the shared Firebase project once the Security Rules were updated.

- Firebase Authentication handles passwords, so no passwords are stored in our database.
- All Firebase settings are kept in one file (firebase-config.js), which made connecting to the team's project quick.
- The pages use the same names as the rest of the team (users, application, brokerID, Broker, Borrower), so AL-Web and AL-Mobile share the same data.

What didn't go well

- **Understanding the deliverables took time.** At the start I was not fully sure what was needed for each user story (wireframe, test case, design).
- **Work was redone.** The first versions stored data in the browser and then in a text file before moving to Firebase.
- **The database was locked.** The Firestore rules blocked all reads and writes, so sign-up could not save roles until new rules were agreed and published.
- **Not built in React yet.** The brief asks for React with React Router and Tailwind CSS. Sprint 1 was built in plain HTML and JavaScript to get working quickly.

What I learned

- The difference between Firebase Authentication (who you are) and Firestore (your data and role).
- Security Rules are what actually protect the data, not hiding the API key.
- Agreeing the data model with the team early saves rework.
- How to write user stories, acceptance criteria and test cases that can be checked.

Future actions for Sprint 2

- Move AL-Web to React with React Router and Tailwind CSS, keeping the same Firebase code.
- Make the status, LTV and risk tier filters work
- Clean up test users in Firestore and fix the role field on the hand-made test user
- Decide how underwriter accounts are approved
